[How does Python's super \(\) work with multiple inheritance?](#)

In fact, multiple inheritance is the only case where super() is of any use. I would not recommend using it with classes using linear inheritance, where it's just useless overhead.

python

If we're using a class method, we don't have an instance to call super with. Fortunately for us, super works even with a type as the second argument. --- The type can be passed directly to super as

['super' object has no attribute '__sklearn_tags__'](#)

'super' object has no attribute '__sklearn_tags__'. This occurs when I invoke the fit method on the RandomizedSearchCV object. I suspect it could be related to compatibility issues

As for chaining `super::super`, as I mentioned in the question, I have still to find an interesting use to that. For now, I only see it as a hack, but it was worth mentioning, if only for the differences with Java

super () in Java

`super()` is a special use of the `super` keyword where you call a parameterless parent constructor. In general, the `super` keyword can be used to call overridden methods, access hidden
